ABSTRACT
This paper presents experimental results on websites of four universities investigated with the aim of drawing up lists of pages and links. Variants of functions approximating the experimental data are considered. The resulting approximation estimates indicate that the approximating functions proposed are of high precision.

Categories and Subject Descriptors
G.2.2 [Discrete Mathematics]: Graph Theory – graph algorithms.

General Terms
Measurement, Experimentation.

Keywords
Web-site, approximation, hyperlinked structure of the site, webometrics, web-graph.

1. INTRODUCTION
Today, you can hardly come across an organization that does not have its own website. In a sense, a website is the face of an organization and the quality is of great importance. The quality of a website consists of many components – page count, page design, page content, and site structure.

A website structure is usually presented in the form of a directed graph whose nodes are documents and whose edges are links connecting these documents [1]. Many researchers today study the global structural characteristics of information networks on the Web. For example, Broder A. and Kumar F. [1] represented large website communities in the form of a strongly connected graph component, components In, Out and Tubes; [2]-[5] deal with distribution of external links and citation index of various university sites; authors in [6] introduce site connectivity characteristics; [7] is dedicated to the study of the method of automatic classification of links and pages by their characteristics; and others.

This paper aims at studying a website structure. More precisely, it tries to identify the kind of functional dependence that exists between the page count of a site and the internal link count of that site.

2. HYPOTHESIS VERIFICATION
2.1 Problem statement
Special crawler [8] was used to solve this problem. In scanning the site, the robot creates two lists: a list of found pages (web graph nodes) and a list of links connecting the found pages (web graph edges).

An act of finding \( e \) links will be considered as a step of the scanning algorithm. That is, \( E_i = e \cdot i \) links are found after \( i \) steps. Let us denote with \( v_i = v(E_i) \) the number of pages found after \( i \) steps. We denote the number of all the links and the number of all pages found in the site with \( e_0 \) and \( v_0 \) respectively. The search robot can find not only the number of pages and links in the site, but also get a graph of the \( v(e) \) function.

Obviously, \( v \leq e \). Here, \( v_0 < e_0 \) (it is very rare when \( v_0 = e_0 \) for websites). It is also obvious that increase in \( v(e) \) is gradually slowed down. This is due to the fact that with increasing number of found pages, the likelihood that the next link will point to a page already found increases.

Let us try and choose an analytic function approximately describing experimental function \( v(E) \), with the following properties:

1. Passes through the origin in the plane \((e, v)\).
2. Increases with an increase in \( e_0 \).
3. Derivative of the function decreases.
4. The function has a simple form and is dependent on a small number of parameters.

2.2 Experiment
Let’s compare the function with experimental set
\[ V_i, E_i (i = [1, N]), \] where \[ N = \left\lfloor \frac{t_0}{e} \right\rfloor. \] We investigated the websites of four universities and obtained the following sets (Table 1).

To assess the approximation quality, we will use average relative error:
\[ \Delta = \frac{1}{N} \sum_{i=1}^{N} \frac{|V_i - v_i|}{v_i}. \]

Next, we consider three possible approximating functions:
\[ v^{(1)} = \alpha \cdot E^\beta, \]
\[ v^{(2)} = \frac{\alpha \cdot E}{E + \beta}, \]
\[ v^{(3)} = \alpha \cdot (\ln(1 + E))^\beta. \]

Let us examine them one by one:

1) We take the logarithm of the equation:
\[ \ln v^{(1)} = \ln \alpha + \beta \cdot \ln E. \]
This gives a system of linear equations
\[ x + A_i \cdot y = B_i, \quad i = [1, N], \]
where \[ x = \ln \alpha, \quad y = \beta, \quad A_i = \ln E_i, \quad B_i = \ln V_i. \]
Its solution with method of least squares:
\[ \alpha = \exp \left( \frac{C_1 C_4 - C_2 C_3}{N (C_1^2 - C_3)}, \right), \quad \beta = \frac{C_1 C_2 - C_4}{C_1^2 - C_3}, \]
where
\[ C_1 = \sum_{i=1}^{N} A_i, C_2 = \sum_{i=1}^{N} B_i, C_3 = \sum_{i=1}^{N} A_i^2, C_4 = \sum_{i=1}^{N} A_i B_i. \]

2) System of linear equations:
\[ \alpha \cdot E_i - \beta \cdot V_i = V_i, \quad i = [1, N]. \]
Its solution with method of least squares:
\[ \alpha = \frac{a_2 \cdot a_4 - a_2 \cdot a_5}{a_1 \cdot a_4 - a_1 \cdot a_2}, \quad \beta = \frac{a_2 \cdot a_3 - a_1 \cdot a_5}{a_1 \cdot a_4 - a_1 \cdot a_2}, \]
where
\[ a_1 = \sum_{i=1}^{N} E_i, \quad a_2 = \sum_{i=1}^{N} E_i V_i, \quad a_3 = \sum_{i=1}^{N} E_i^2, \quad a_4 = \sum_{i=1}^{N} V_i, \quad a_5 = \sum_{i=1}^{N} V_i E_i. \]

3) We take the logarithm of \( v^{(3)} \):
\[ \ln v^{(3)} = \ln \alpha + \beta \cdot \ln \ln(1 + E). \]
We get a system that almost coincides with the first case. Its solution will be the same, except that in the first case \( A_i = \ln E_i \), while in this case,
\[ A_i = \ln \ln(1 + E_i). \]

2.3 Results of the experiment
Figures 1, 2, 3 and 4 present the graphs of functions \( v^{(1)}, v^{(2)}, v^{(3)} \) and \( V \), for each of the universities listed.
Table 2 shows the relative errors of each of the formulas for each of the universities.

### Table 2. Average relative error of functions $v^{(1)}, v^{(2)}, v^{(3)}$ for each university

3. CONCLUSION

The paper considered the problem of finding a function that approximates the experimental graph of dependence of web page count on link count. Three approximations were proposed. It was revealed that the best approximations are obtained for power and linear fractional function. The functions proposed can be used to study the parameters of sites and their clustering.
